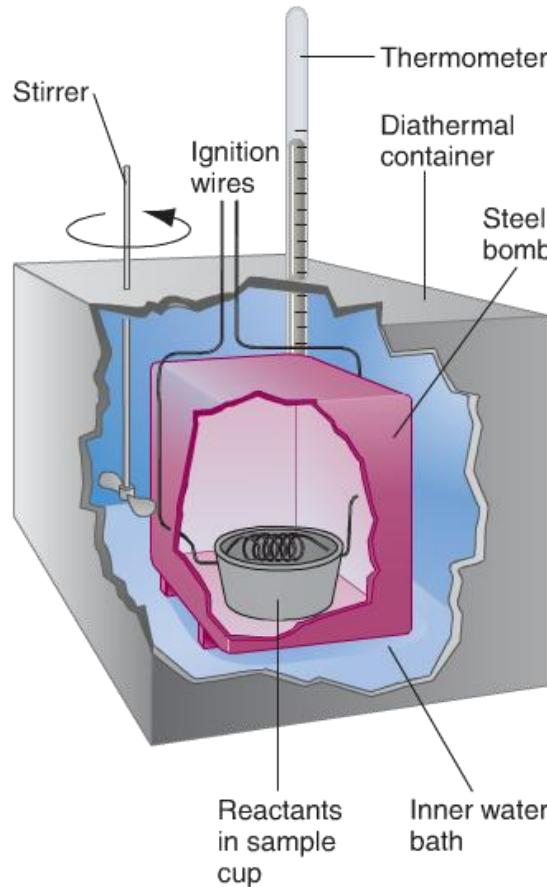

FIGURE 4.3

Schematic diagram of a bomb calorimeter. The liquid or solid reactant is placed in a cup suspended in the thick-walled steel bomb, which is filled with O₂ gas. The vessel is immersed in an inner water bath, and its temperature is monitored. The diathermal container is immersed in an outer water bath (not shown) whose temperature is maintained at the same value as the inner bath through a heating coil. By doing so, there is no heat exchange between the inner water bath and the rest of the universe.

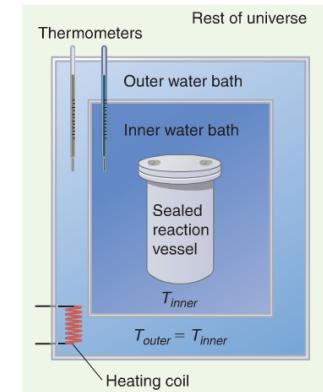

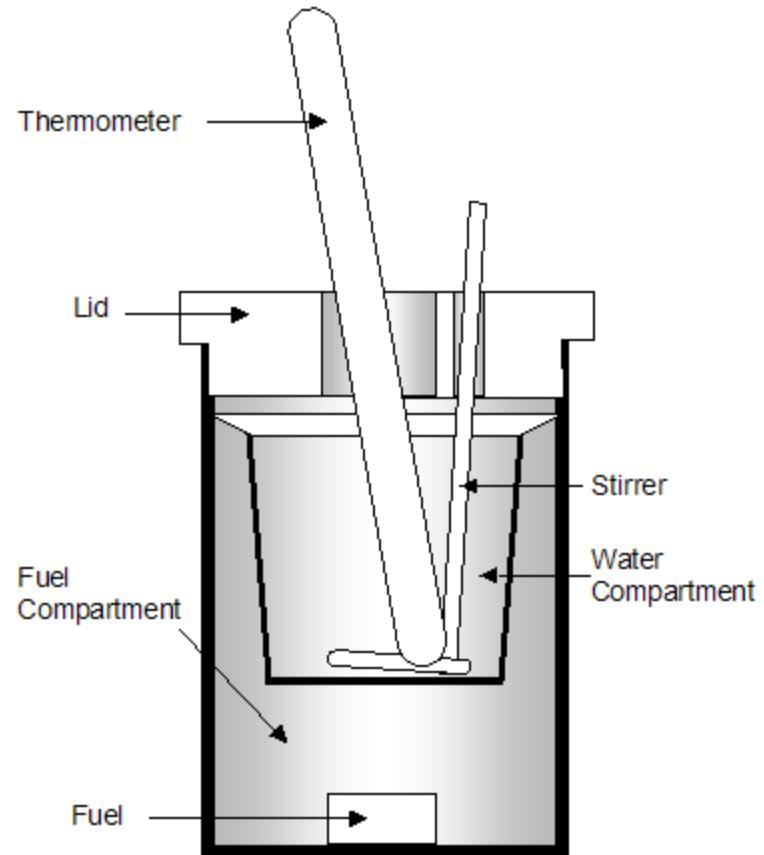

FIGURE 2.3

An isolated composite system is created in which the surroundings to the system of interest are limited in extent. The walls surrounding the inner water bath are rigid.

$\Delta H_{\text{reaction}}$ vs $\Delta U_{\text{reaction}}$ at fixed temperature T

$$H \equiv U + PV$$

$$\Delta H = H_{\text{prods}} - H_{\text{reacts}}$$

$$\Delta H = \Delta U + \Delta(PV) = \Delta U + (PV)_{\text{prods}} - (PV)_{\text{reacts}}$$

assume:

- i) PV and ΔPV is small for solids and liquids
- ii) Gasses follow ideal gas law

$$\Delta PV = (PV)_{\text{prods}} - (PV)_{\text{reacts}}$$

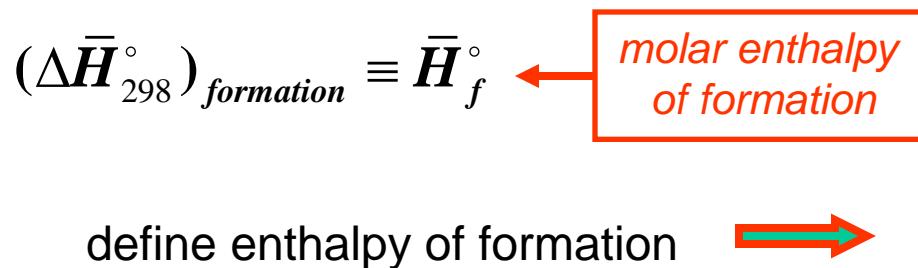

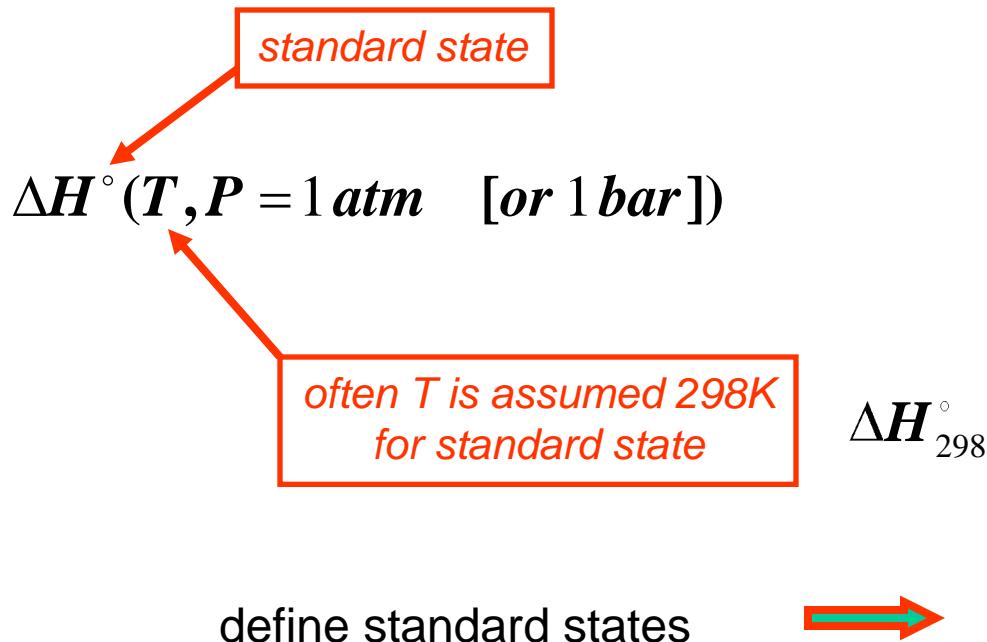

$$\Delta PV = (n_{\text{gas}}RT)_{\text{prod}} - (n_{\text{gas}}RT)_{\text{react}}$$

$$\Delta PV = \Delta n_{\text{gas}} RT$$

bond enthalpy vs bond energy

- often [mis]used interchangeably
Usually both meant to mean bond **enthalpy**
- bond **enthalpy**: thermodynamic heat measured at const P
- bond **energy**: the bond strength from quantum mechanical calculation
- can be interconverted by the $\Delta H = \Delta U + \Delta n_{\text{gas}} RT$ relation (p. 68; example problem 4.1 for O-H bond *bond energy*= 461 kJ mol^{-1} vs *bond enthalpy*=463.5 kJ mol^{-1})
