***Fall 2016***

Sessions ~~Lectures~~ 15-16

Covalent Bonding and Geometry  
in Polyatomic Molecules

- WE WILL NOW BE COVERING THE FIRST PART OF CHAPTER 14 (pp 663-676) AND THEN (688-692)
- You will go **CRAZY** unless you concentrate on the material presented in lecture and homework

- similar to bonding in diatomic molecules in that ao's on one atom constructively interfere with on second atom to form bonds
- new twist is that the covalent bonds **can involve more than one ao on each atom** (we had a taste of this with the extra 2s-2p interactions in the B<sub>2</sub>, C<sub>2</sub>, N<sub>2</sub> diatomics)

*what "bonds" would atoms in their ground atomic states form ?*

---

**bonding with H •**

expected from  
atomic configuration

**no bonds**

**but BeH<sub>2</sub> exists**

**but also BH<sub>3</sub>**

**but also CH<sub>4</sub>**

**also H<sub>2</sub>O and HF**

also what does qm have to say about bond angles

has the  $2p^3$  electron in orbitals which are at  $90^\circ$

BUT

H-N-H angle =  $90^\circ$

H-N-H angle =  $107^\circ$

## *so what's wrong with electrons in atomic configuration ???*

---

Observed increased stability (lower energy) over 'atomic' ground state configuration via:

- **formation of additional covalent bonds**
- **arrangement of electron groups to minimize repulsion**

How does one account for:

- formation of additional bonds over what would be expected from atomic electron configuration
- bond angles different than those between atomic [p]orbitals

*quantum mechanics to the rescue !!!!!*

---

## ORBITAL HYBRIDIZATION

In forming covalent bonds an atom may use higher energy ao's which are not occupied in the ground state of the isolated atom.

### Energy costs (disadvantages of hybrid orbitals)

- uses 'higher' energy ao's

### Energy gains (advantages of hybrid orbitals)

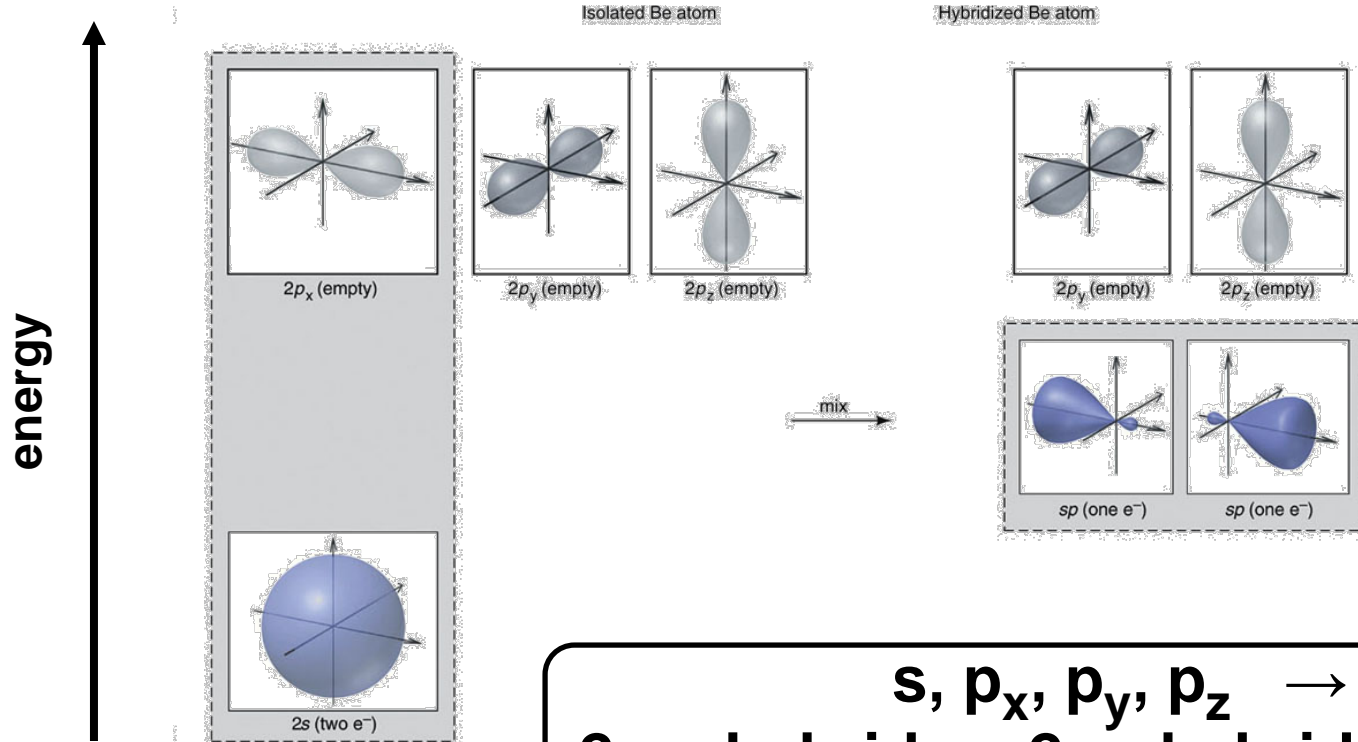

- form more covalent bonds than in atomic configuration
- gives geometry where electron groups minimize repulsion (a la VSEPR)
- gives better overlap (constructive interference between orbitals on two atoms forming a bond)

Zumdahl:  $sp^3 \rightarrow sp^2 \rightarrow sp$  ☹️

US:  $sp \rightarrow sp^2 \rightarrow sp^3$  😊

# *sp hybridization in BeH<sub>2</sub> (Silberberg fig 11.2)*

# formation of Be-H bonds

---

# *BeH<sub>2</sub> description of bonds*

---

- The 'first' step of hybridization involves combining orbitals on **A SINGLE** atom. This may involve orbitals which do not have **NET** overlap (e.g. 2s and 2p) to get the hybrid orbitals (e.g.  $sp_+$  and  $sp_-$ )
- Since there is no net interference, this step involves **NO** change of energy from that of the average of the a.o. energies [i.e. sp hybrids have average energy of  $\frac{1}{2} (E_{2s} + E_{2p})$  ]
- Bonding occurs when the **hybrids on TWO** atoms constructively interfere to give a lower energy localized m.o. (a chemical bond)

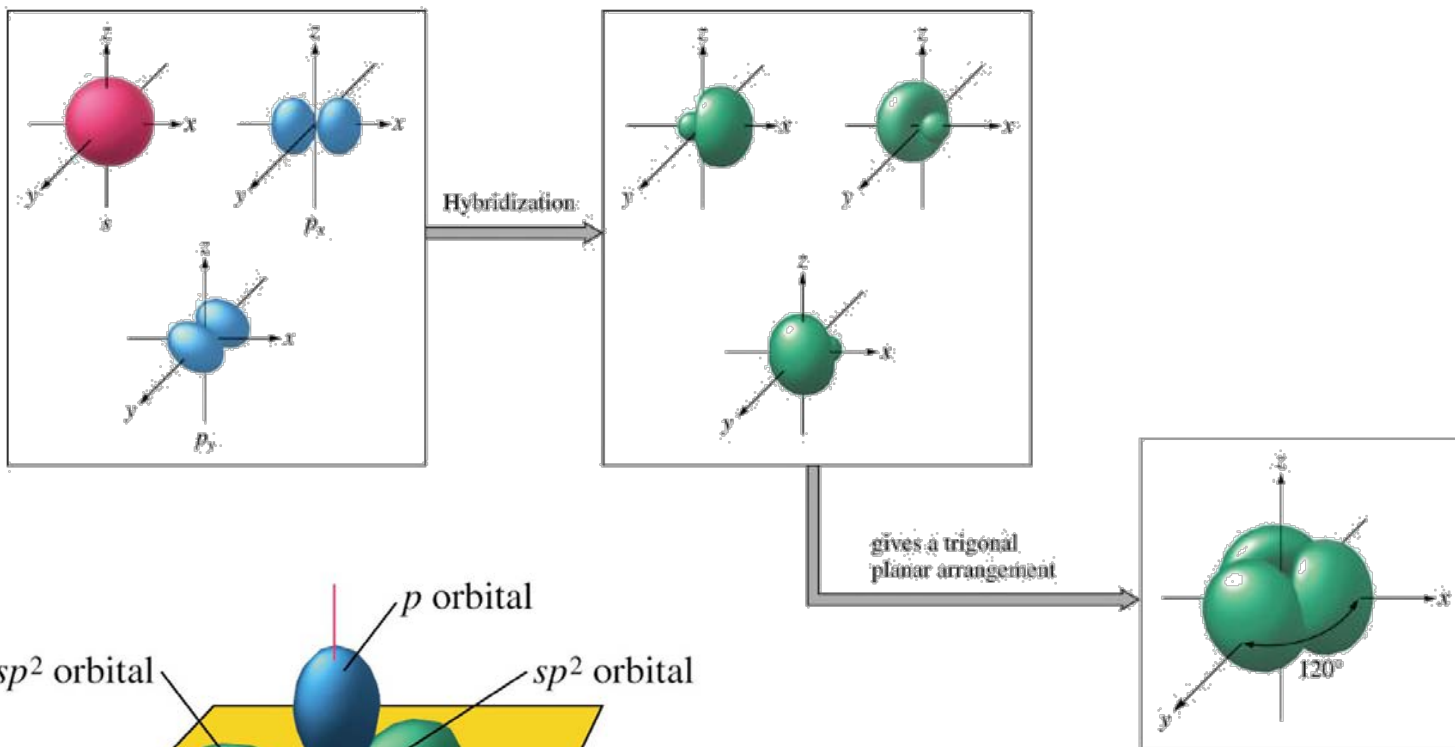

bonding in  $BH_3$  ----  $sp^2$  hybrids (figure 14.9)

**S,  $p_x$ ,  $p_y$ ,  $p_z$  →  
3  $sp^2$  hybrids +  
1 unhybridized p ao**

# geometry of $sp^2$ hybrids (figure 14.8, 14.10)

©Houghton Mifflin Company. All rights reserved.

[Dr. Gutow's Hybrid Atomic Orbital Site](#)

## geometry of $sp^2$ hybrids

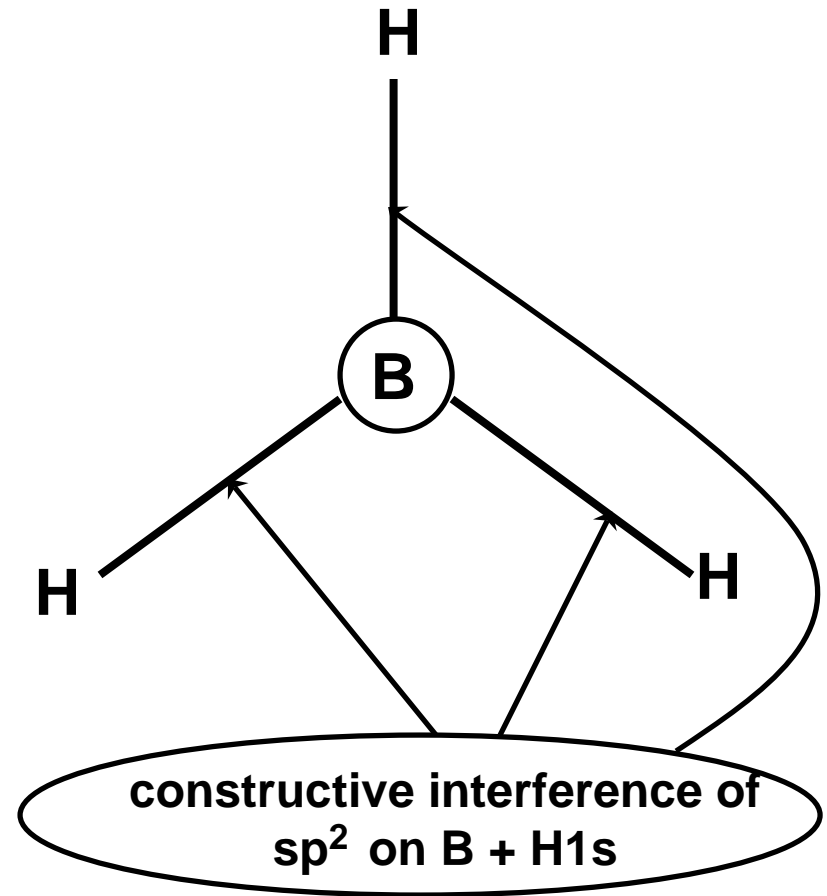

---

- the 3  $sp^2$  hybrids are in a plane with  $120^\circ$  angles between them
- this results in trigonal planar geometry for the bonds formed by the hybrids
- the unhybridized p is perpendicular to the plane

*bonding in  $BH_3$  : trigonal planar geometry*

Chemistry 1B-AL Fall 2016, Study Guide and Worksheet IX

## Learning Objectives and Worksheet IX

### Chemistry 1B-AL Fall 2016

#### Sessions Lectures (15-16) Bonding in Polyatomic Molecules:

RETURNING TO THE FIRST PART OF CHAPTER 14 (pp. 633-676), to cover covalent bonding in polyatomic molecules, and then onto molecular dipoles (pp 688-692).

In the previous class sessions we have investigated how covalent bonds are formed by the constructive interference of atomic orbitals on two atoms in a diatomic molecule. Now we are prepared to extend these concepts to polyatomic molecules.

#### I. Ground state atomic configurations do not predict molecular structures

1. In the  $H_2$  molecule we saw how atomic orbitals containing an unpaired electron on each H atom interact to form a bonding molecular orbital that accommodated the electron-pair. For the atoms below, indicate the formulas of the hydrides that would be formed by an H-atom combining with unpaired electrons in the atom's ground state to form  $XH$  bonds.

- i. Li
- ii. Be
- iii. B
- iv. C
- v. N

2. In the ground state of atomic nitrogen,  $1s^2 2s^2 2p_x 2p_y 2p_z \uparrow \uparrow \uparrow$ , 3 H- atoms could interact with the unpaired electrons in the 2p orbitals to form the stable octet structure  $NH_3$ . From your knowledge of the geometry of the  $2p_x$ ,  $2p_y$ , and  $2p_z$  orbitals the predicted H-N-H bond angle would be \_\_\_\_\_°.

#### II. General principles of hybridization

1. In forming covalent bonds in polyatomic molecules hybrid orbitals may be utilized. A hybrid orbital consists of \_\_\_\_\_ that may include both occupied and unoccupied in the atom's ground state configuration.
2. In forming hybrids what are the "costs" in terms of energetics (i.e. higher energy relative to atom): \_\_\_\_\_ would be a cost of forming hybrids. This is why isolated atoms do not "naturally" go to a hybridized state.

1

Chemistry 1B-AL Fall 2016, Study Guide and Worksheet IX

3. There are several energetic advantages accrued (lowering of energy) when an atom utilizes hybrids to form covalent bonds in a polyatomic molecule. These include:

- i. \_\_\_\_\_
- ii. \_\_\_\_\_
- iii. \_\_\_\_\_

4. We will see that whether a molecular structure involves primarily atomic or hybrid orbitals depends on the "winner" of the energy costs vs energy gains. In describing the m.o. of diatomic molecules we focused on combinations of unhybridized atomic orbitals. However s-p mixing or sp hybridization was invoked for the energy ordering for B, C, N, but not O, or F. In terms of energy costs vs gains, why would s-p mixing occur for the lower atomic number 2<sup>nd</sup> row atoms but not for Z=8 or 9?

5. A bonding orbital between a hybrid orbital on boron atom and a H- atom is formed by \_\_\_\_\_ between the hybrid orbital and a 1s a.o. on the H- atom.

#### III. sp hybridization

1. In sp hybridization the  $2s$ ,  $2p_x$ ,  $2p_y$ , and  $2p_z$  a.o. form \_\_\_\_\_ sp hybrids leaving \_\_\_\_\_ unhybridized 2p orbitals.
2. The sp hybrids are directed \_\_\_\_\_° apart and the unhybridized 2p a.o.'s are \_\_\_\_\_ to the direction of the sp hybrids.
3. If H- atoms bond with unpaired electrons in the sp hybrids the resulting molecular geometry is \_\_\_\_\_.

Bonding in acetylene  $C_2H_2$  applet (helps with HW#7, 51):

<http://switkes.chemistry.ucsc.edu/teaching/1mol/AcetyleneBonding/AcetyleneBonding.html>

#### IV. sp<sup>2</sup> hybridization

1. In sp<sup>2</sup> hybridization the  $2s$ ,  $2p_x$ ,  $2p_y$ , and  $2p_z$  a.o. form \_\_\_\_\_ sp<sup>2</sup> hybrids leaving \_\_\_\_\_ unhybridized 2p orbital.
2. The sp<sup>2</sup> hybrids are directed \_\_\_\_\_° apart and the unhybridized 2p a.o. is \_\_\_\_\_ to the plane of the sp<sup>2</sup> hybrids.
3. If H- atoms bond with unpaired electrons in the sp<sup>2</sup> hybrids the resulting molecular geometry is \_\_\_\_\_.

2

# this video: worksheet 10-9 sections VI-VII

Chemistry 1B-AL Fall 2016, Study Guide and Worksheet IX

## V. $sp^2$ hybridization

1. In  $sp^2$  hybridization the 2s, 2p<sub>x</sub>, 2p<sub>y</sub>, and 2p<sub>z</sub> a.o. form \_\_\_\_\_  $sp^2$  hybrids leaving \_\_\_\_\_ unhybridized 2p orbitals.
2. The  $sp^2$  hybrids are directed \_\_\_\_\_° apart.
3. If H- atoms bond with unpaired electrons in the  $sp^2$  hybrids the resulting molecular geometry is \_\_\_\_\_.

Excellent website to visualize  $sp^3$  hybrids:

[http://www.uwosh.edu/faculty\\_staff/gutow/Orbitals/N/sp3%20hybrid.shtml](http://www.uwosh.edu/faculty_staff/gutow/Orbitals/N/sp3%20hybrid.shtml)

## VI. Bonding in molecules with more than one 2<sup>nd</sup> row atom

1. In the molecule n-propane  $CH_3CH_2CH_3$ 
  - i. the geometry around the central carbon would be \_\_\_\_\_.
  - ii. the C-C bonds would be the result of constructive interference between \_\_\_\_\_.
  - iii. the C-H bonds would be the result of constructive interference between \_\_\_\_\_.
2. In the molecule propene  $CH_3CH=CH_2$ 
  - i. the geometry around the central carbon would be \_\_\_\_\_.
  - ii. the C=C bond[s] would be the result of constructive interference between
    - a. \_\_\_\_\_ and \_\_\_\_\_ (for one component of double bond)
    - b. \_\_\_\_\_ and \_\_\_\_\_ (for the second component).
  - iii. the C-C single bond would be the result of constructive interference between \_\_\_\_\_.

## VII. When might an atomic bond with unhybridized a.o.'s?

1. The geometry of some molecules with third row central-atoms indicates that the atom is forming bonds with predominantly unhybridized a.o.'s. Why might this be so in terms of the costs and advantages of hybridization?

3

Chemistry 1B-AL Fall 2016, Study Guide and Worksheet IX

## V. $sp^2$ hybridization

1. In  $sp^2$  hybridization the 2s, 2p<sub>x</sub>, 2p<sub>y</sub>, and 2p<sub>z</sub> a.o. form \_\_\_\_\_  $sp^2$  hybrids leaving \_\_\_\_\_ unhybridized 2p orbitals.
2. The  $sp^2$  hybrids are directed \_\_\_\_\_° apart.
3. If H- atoms bond with unpaired electrons in the  $sp^2$  hybrids the resulting molecular geometry is \_\_\_\_\_.

Excellent website to visualize  $sp^3$  hybrids:

*to hybridize or not to hybridize*

---

to hybridize or not to hybridize

that is the question?

Bond angles : H<sub>2</sub>O (105°) vs H<sub>2</sub>S (92.2°)  
NH<sub>3</sub> (107°) vs PH<sub>3</sub> (93.4°) →

- As the central atom becomes larger the bond angles reflect unhybridized p orbital aos.
- These are cases where hybridization would be driven by reduction of electron group repulsion and increased bonding overlap (same number of bonds if unhybridized or hybridized).
- As the central atom gets larger, the repulsion between electron groups (e.g. lone pairs) decreases and thus the atom is more likely to remain unhybridized.

to hybridize or not to hybridize

that is still the question?

*“terminal” atoms bonded to only one other atom  
(no clues from molecular geometry, i.e. molecular shape)*

---

B is sp<sup>2</sup>

what's the hybridization  
of the F's ?

sp<sup>2</sup> on B + ? on F

hybridization at C is sp<sup>2</sup>

what about = $\ddot{\text{O}}$  ?  
sp<sup>2</sup> or unhybridized ??

C=O

σ: sp<sup>2</sup> on C + ? on O  
π: p<sub>π</sub> on C + p<sub>π</sub> on O

when there is no experimental structural evidence, the state of hybridization state in terminal atoms is often obtained from quantum mechanical calculations

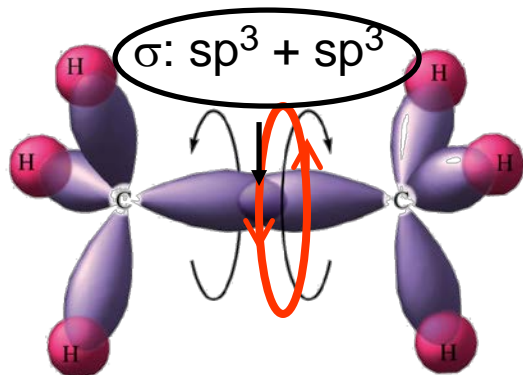

in our next class session, we will look at some examples and come to an “agreement” on what are appropriate specifications for the state of hybridization for various bonding situations

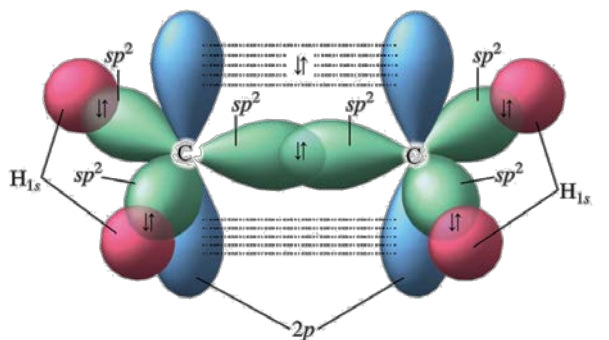

[no] rotation around double bond (figs 21.7 and 21.8)

single

'free' rotation about single bond ↓

double

**Note that the extra, overlapping pi-bond prevents free rotation around the double bond. One would have to break the pi-bond to be able to rotate around the sigma bond.**

no rotation around double bond

*dipole moments of geometric isomers (cis 1,2 dichloroethylene [cis 1,2 dichloroethene])*

---

***net dipole direction***

***cis 1,2 dichloroethylene*** →

*trans 1,2 dichloroethylene* →

## double bonds and geometric isomers

---

vs

**cis** 1,2 dichloroethylene

**trans** 1,2 dichloroethylene

will not interconvert under 'normal' conditions

net dipole 

no net dipole •

# Finis

and

## 'free' rotation around a single bond

---

'free' rotation around single bond of ethane

*maybe not so free !!  
pair-share exercise*

**no** geometric isomers normal conditions (1,2 dichloroethane)

---

no geometric isomers

## double bonds and geometric isomers

**geometric isomers:** two or more compounds which contain the same number and types of atoms, and bonds (i.e., the connectivity between atoms is the same), but which have different spatial arrangements of the interatomic distances between atoms and thus have differing physical and chemical properties

**cis** 1,2 dichloroethylene

**trans** 1,2 dichloroethylene

will not interconvert under 'normal' conditions

# [no] rotation around double bond

but does “no” mean  
“never” ?

*hybridization or not: 2<sup>nd</sup> row vs 2<sup>rd</sup> row*

---

H<sub>2</sub>O

H<sub>2</sub>S

NH<sub>3</sub>

PH<sub>3</sub>

to hybridize or not to hybridize

that is still the question?

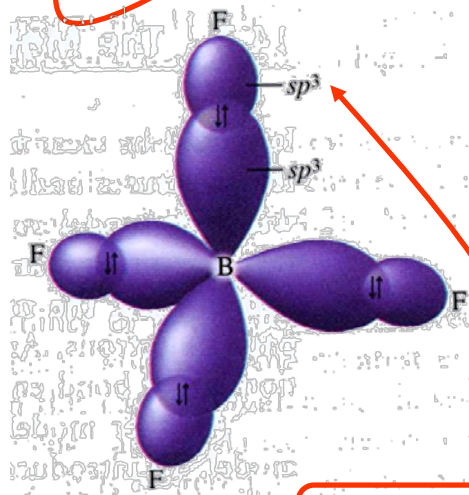

atoms bonded to only one other atom  
(no clues from molecular geometry, i.e. molecular shape)

B is  $sp^2$

what's the hybridization  
of the F's ?

$sp^2$  on B +  $sp^3$  on F

Zumdahl: F is  $sp^3$

Other texts:  
F remains unhybridized

atoms bonded to only one other atom (figur 14.15 and 14.19)

hybridization at C is  $sp^2$

what about  $=\ddot{O}$  ?  
 $sp^2$  or unhybridized ??

**C=O**  
 $\sigma$ :  $sp^2$  on C +  $sp^2$  on O  
 $\pi$ :  $p_\pi$  on C +  $p_\pi$  on O

Zumdahl:  $sp^2$

more on oxygen (DGH)

unhybridized ao's  
on =O
